# Instructions on How This Works

A simple Windows setup and run guide for NSE_EXTRACTOR

## 1. Install Python and add it to PATH

Download the normal **64-bit Windows version of Python 3.13.14** from python.org/downloads/windows.

Open the installer, tick **Add python.exe to PATH**, then click **Install Now**. Close and reopen PowerShell after installation.

```
python --version
```

## 2. Open PowerShell and use the basic commands

Press the Windows key, type **PowerShell**, and open it. These are the commands you need:

| Command | What it does |
|---|---|
| **pwd** | Shows your current folder. |
| **dir** | Lists the files and folders here. |
| **cd "full folder path"** | Moves into that folder. |
| **cd ..** | Moves back one folder. |

## 3. Enter the project folder, add companies, install once, and run

Keep **NSE.py**, **companies.xlsx**, and **requirements.txt** together inside the NSE_EXTRACTOR folder.

**Before running:** open **companies.xlsx**, add the company names in column B under **Name**, then save and close the Excel file.

Change the example path below to the real path on that laptop.

```
cd "C:\Users\YourName\Downloads\NSE_EXTRACTOR"
python -m pip install --upgrade pip
python -m pip install -r requirements.txt
python -m playwright install chromium
python NSE.py
```

The three installation commands are needed only once. For future runs, open PowerShell, use **cd** to enter NSE_EXTRACTOR, then run **python NSE.py**.

If Windows recognizes **py** instead of **python**, replace python with py in every command.

## 4. Where the output will be

A new timestamped run folder is created automatically here:

```
NSE_EXTRACTOR\outputs\YYYY-MM-DD_HH-MM-SS\
```

Inside it, each company gets its own folder containing the downloaded PDFs and final Excel/JSON reports. The **.nse_browser_profile** folder is also created automatically; leave it in place.

**PowerShell tip:** Press Ctrl + C to stop the current running process.
